**STAGED OIL FILTER INCORPORATING PELLETIZED BASIC CONDITIONER**

5

**BACKGROUND OF THE INVENTION****1. Field of the invention**

The present invention relates to an oil filter apparatus for use in conjunction with an internal combustion engine. More particularly, the present invention relates to an oil filter apparatus including both a mechanically active filter element and a chemically active filter element incorporated therein. Even more particularly, the present invention relates to an oil filter of the type described, in which a chemically active filter element includes pellets formed of a basic conditioner intermixed with a polymeric binder, for counteracting acidic combustion products in engine oil.

15 **2. Description of the Background Art**

Many different types of fluid filters are known. Most such filters use a mechanical or 'screening' type of filtration, with a replaceable cartridge having a porous filter element therein.

In the oil filtration art, it is well known that normal operation of an internal combustion engine, particularly a diesel engine, results in the formation of contaminants. These contaminants include, among others, soot, which is formed from incomplete combustion of the fossil fuel, and acids that result from combustion. Both of these contaminants are typically introduced into the lubricating oil during engine operation, and tend to increase oil viscosity and to generate unwanted engine deposits, leading to increased engine wear.

The conventional solution to these problems has been to place various additives into lubricating oils. In order to combat soot-related problems, many conventional lubricating oils

25

include dispersants that resist agglomeration of soot therein. These work well for a short period, but may become depleted. Additionally, due to the solubility and chemical stability limits of these dispersants in the oil, the service lives of the lubricating oil and the oil filter are less than optimal.

For combating combustion acid related problems, many conventional systems include

5 neutralizing additives known as over-based detergents. These are a source of TBN (total base number), which is a measure of the quantity of the over-based detergent in the oil. The depletion of the TBN is an important limiting factor for many internal combustion engines, and in particular for heavy-duty applications with diesel engines.

In order to improve engine protection and to combat other problems, conventional  
10 lubricating oils often include one or more further additives, which may be corrosion inhibitors, antioxidants, friction modifiers, pour point depressants, detergents, viscosity index improvers, anti-wear agents, and/or extreme pressure additives. The inclusion of these further additives may be beneficial; however, with conventional methods, the amount and concentration of these additives are limited by the ability of lubricating oils to suspend these additives, as well as by the  
15 chemical stability of these additives in the oil.

Other solutions have been proposed in addition to the conventional method of mixing additives with lubricating oil. For example, in order to combat the build up of sludge in oil, US Patent 5,478,463, issued in 1995 to Brownawell et al, and entitled Method of Reducing Sludge and Varnish Precursors in Lubricating Oil; and US Patent 5,042,617, issued in 1991 to  
20 Brownawell, and entitled Method of Reducing the Presence of Sludge in Lubricating Oils, each disclose an oil filter and method for reducing the amount of sludge in lubricating oil as it circulates throughout an engine. These Brownawell patents provide for the inclusion of particles in an oil

filter that are oil insoluble and oil wettable, and which complex with sludge such that at least some of the sludge that these particles come into contact with is immobilized on the particles. The Brownawell '617 patent discloses the inclusion of oil insoluble and oil wettable particles in an oil filter that are retained on a pelletized substrate, whereas the Brownawell '463 patent discloses the inclusion of such particles that are not retained on a substrate, but are nonetheless retained in the oil filter.

Another Brownawell patent, which relates to the reduction of combustion acids in lubricating oil, is US Patent 5,069,799 issued in 1991 and entitled Method For Rejuvenating Lubricating Oils. This Brownawell patent discloses an oil filter and method for reducing the amount of combustion acids in lubricating oil. In particular, it discloses a method of rejuvenating lubricating oil, which includes reduction of combustion acids, by serially passing the oil through first a chemically active filter media, then a physically active filter media, and finally an inactive filter media. In this '799 patent, the chemically active filter media includes a strong base, to displace weak bases that have combined with combustion acids. The combustion acid and the strong base then combine to form a salt, which is then physically trapped by subsequent mechanical filter media.

U.S. patent number 5,225,081 to Brownawell discloses method of removing polynuclear aromatics from used lubricating oil. The method of the Brownawell '081 reference involves passing oil through a staged oil filter system, which may include a chemically active filter media. The chemically active filter media is made of a composite material including particles of an active component and a thermoplastic binder, which are a product of a heated extrusion process. Basic conditioners are given as one example of materials suitable for use as materials usable as

chemically active filter media. Activated carbon is also emphasized as a preferred component of the filter media.

Some designs for multiple stage oil filters are known, such as those disclosed in U.S. patent numbers 4,557,829 and 4,886,599. U.S. patent number 4,886,599 to Bachmann et al.

5 discloses a filter cartridge with sequential concentric cylindrical filter elements, for both chemical and mechanical filtration of oil contained in an oil-sealed vacuum pump.

Other designs for oil filters that contain extra additives and dispense those additives into oil, over time, are disclosed in U.S. patent numbers 4,075,098 and 5,552,040.

A need still exists in the art for an improved oil filter having a basic conditioner  
10 incorporated therein to counteract the effects of acidic combustion products in the oil. A need also exists for an improved oil filter which could extend the useful life of engine oil, so as to allow a user to extend the time interval between oil changes in a vehicle, particularly a vehicle having a diesel engine.

### SUMMARY OF THE INVENTION

15 The present invention provides an improved oil filter having a basic conditioner incorporated therein. The basic conditioner is provided to counteract the effects of acidic combustion products in the oil. In a preferred embodiment of the invention, the basic conditioner is provided in the form of a plurality of pellets disposed within the oil filter housing.

In a preferred embodiment of the invention, these pellets are a product of a process in  
20 which a finely divided thermoplastic binder is mixed with a granular or particulate form of a basic additive in the presence of an organic solvent. After thorough mixing, the mixture is formed into pellets, and then the solvent is evaporated from the pellets.

It is an advantage of the present invention that by forming the pellets by the above-described process, a high percentage of the active basic conditioner in the pellet may be achieved.

Accordingly, it is an object of the present invention to provide an improved oil filter including a pelletized basic conditioner.

5 It is a further object of the present invention to provide a method of making an improved oil filter of the type described.

For a more complete understanding of the present invention, the reader is referred to the following detailed description section, which should be read in conjunction with the accompanying drawings. Throughout the following detailed description and in the drawings, like  
10 numbers refer to like parts.

#### **BRIEF DESCRIPTION OF THE DRAWINGS**

Figure 1 is a perspective view, partially cut away, of an oil filter in accordance with a first embodiment of the present invention;

Figure 2 is a cross-sectional view of the filter of Figure 1;

15 Figure 3 is a flow chart showing a series of steps in a preferred method of forming an oil filter according to the invention;

Figure 4 is a cross-sectional view of an oil filter according to a second embodiment of the present invention;

20 Figure 5 is a cross-sectional view of an oil filter according to a third embodiment of the present invention;

Figure 6 is an exploded cross-sectional view of a two-part oil filter assembly according to a fourth embodiment of the present invention; and

Figure 7 is a top plan view of a supplemental cartridge, which is a component of the assembly of Figure 6.

### **DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT**

Throughout the present specification, relative positional terms like 'upper', 'lower', 'top',  
5 'bottom', 'horizontal', 'vertical', and the like are used to refer to the orientation of the filters shown in the drawings. These terms are used in an illustrative sense to describe the depicted embodiments, and are not meant to be limitative. It will be understood that in a specific application thereof, a filter may be installed on an engine in an orientation different from that shown in the drawings, such as inverted 180 degrees or transverse to that shown, and in such a  
10 case, the above-identified relative positional terms will no longer be accurate.

Referring to Figures 1 and 2, there is shown an oil filter 10 according to a first preferred embodiment of this invention. The direction of oil flow, through the filter 10, is shown by the arrows in Figure 2, which illustrate a flow path through the filter.

The oil filter 10 generally includes a hollow cylindrical housing 11 which defines a  
15 chamber 14 therein, a porous mechanically active filter element 15 within that chamber, and a chemically active filter element 16, made up of a plurality of individual composite pellets 18, also retained within the chamber inside the housing. A foraminous cylindrical screen or support frame 17 may, optionally, be provided within the housing 11 to supportively hold the filter elements 15, 16 therein. A grommet 19 or other internal sealing member is provided centrally at the base of  
20 the frame 17 to route the oil along the flow path and through the filter elements 15, 16. The grommet 19 may include a flexibly resilient sealing member having an integral pressure relief valve therein, such as that disclosed in co-pending U.S. patent application serial no. 09/271,137, filed

March 17, 1999, the disclosure of which is incorporated by reference. Alternatively, the oil filter 10 may incorporate a spring-loaded or other conventional pressure relief valve of a type known to those in the art.

A base plate 20 of the housing 11 includes a plurality of inlet ports 22 formed therethrough and arranged in a circular pattern. The base plate 20 also includes a central outlet port 24. The outlet port 24 has a plurality of female threads formed therein to allow rotatable mounting of the filter 10 on an externally threaded hollow tubular fitting on an engine block (not shown). An annular external sealing member 25 fits engagingly into a groove 26 formed at the bottom surface of the base plate, to resist oil leakage outwardly from the base of the filter.

In the depicted embodiment 10 of Figs. 1-2, the mechanically active filter element 15 is a conventional cylindrical member made of accordion-pleated filter paper.

The chemically active filter element 16 is also provided in the shape of a cylinder in this embodiment, and is disposed radially and coaxially within the mechanically active filter element 15. In this first embodiment 10 the chemically active filter element 16 is located inside of, and therefore downstream of the mechanical filter element 15, in order to allow a first mechanical filtration to take place before the chemical reaction of unwanted contaminants from the oil with the basic conditioner of the chemical filter element 16. Placement of the chemical filter element 16 between the mechanically active filter element 15 and the frame member 17, as shown in the first filter embodiment 10, puts it downstream from the mechanical filter element, yet still obtains the maximum possible support from the frame member 17. This may be helpful where the chemical filter element 16 is made up of a plurality of separate and unconnected individual pellets 18. Alternatively, the individual pellets 18 making up the chemically active filter element 16 may

be bonded together or otherwise cohesively associated with one another to form a substantially integral, yet highly porous filter element 16 capable of independently supporting itself.

The pellets 18 making up the chemically active filter element 16 are an important feature of the filter 10 hereof. The pellets are made with a diameter in a range of 0.1 to 3 millimeters,

5 preferably in a range of 0.25 to 2 millimeters in order to control the interstitial spaces therebetween in the filter matrix. The size of these interstices is specifically chosen and engineered to screen out most complexes which result from a reaction between combustion acids in the filtered oil and the basic conditioner of the pellets, without substantially reducing the flow rate through the chemically active filter member 16.

10 The pellets are made primarily of a basic conditioner held together with a polymeric binder. Optionally, the pellets may be made exclusively of basic conditioner and binder, in order to maximize the level of active ingredient therein. The basic conditioner of the pellets is preferably a basic salt selected from the group consisting of calcium carbonate, potassium carbonate, potassium bicarbonate, aluminum dihydroxy sodium carbonate, magnesium oxide, magnesium  
15 carbonate, zinc oxide, sodium bicarbonate, sodium hydroxide, calcium hydroxide, potassium hydroxide, and mixtures thereof.

The basic salt is present in the pellets in a range of 80-97 percent by weight of the total pellet weight, preferably 85-97 percent, and most preferably between 90 and 97 percent by weight of the total pellet weight, with the balance being made up by the polymeric binder. Other  
20 materials may be added to the pellets if desired.

Referring now to Figure 3, a series of steps in a first method of making a filter 10 are shown. An early step 30 in the first method hereof is to grind or shred a polymeric binder, if comminution of the binder is needed, so that it is present in a finely divided form.

Preferred binders in the practice of the present invention are thermoplastics. Particularly  
5 preferred binders include polyamides, polyimides, polyesters, polyolefins, polysulfones, and mixtures thereof. If the binder may be obtained in pulverized or granular form, the step 30 of grinding or shredding the binder may be omitted.

Another early step 32 in the first preferred method hereof is to grind or mill the basic conditioner for the pellets, if it is not already provided in particulate form. This step is optional,  
10 and where it is necessary, steps 30 and 32 may be performed in any order.

As noted, materials usable for the basic component, in accordance with the invention, include basic salts selected from the group consisting of calcium carbonate, potassium carbonate, potassium bicarbonate, aluminum dihydroxy sodium carbonate, magnesium oxide, magnesium carbonate, zinc oxide, sodium bicarbonate, sodium hydroxide, calcium hydroxide, and mixtures  
15 thereof.

Once the basic conditioner and the binder are both present in finely divided form, they must be thoroughly mixed, in the presence of a suitable solvent, during a mixing step 34. This is done by mixing the binder into the liquid solvent, stirring, and then subsequently adding the powdered or granular base. The binder is preferred to be present in a range of 3-20 percent of the  
20 solids present, and the basic conditioner is preferred to be present in a range of 90-97 percent of the solids.

Suitable solvents, which may be used in the practice of the present invention, include organic solvents, particularly volatile organic solvents. A minimum amount of solvent which will allow for complete mixing of the solids is preferred.

After mixing is complete, the mixture is formed into pellets in the next step 36. This may  
5 be done by cold extrusion or by any other suitable means known to those in the art.

Once the pellets 18 are formed, the solvent is removed therefrom by evaporation in a drying step 38, and when the pellets are dry, they are installed into the filter housing 11 in a filter assembly step 40.

Using the above-identified solvent-based first preferred method of forming the pellets  
10 according to the invention allows for up to 90-97 percent basic salt, by weight, being present in the finished pellets. This is a higher concentration of the active salt in the pellets than is possible with a pellet forming operation in which a heated mixture is extruded from a die to form a pellet. Typically using the heated extrusion method only allows for a maximum of 50-80 percent active salt, with the balance being the binder.

15 As previously noted, if desired, the pellets may be bonded together or otherwise connected together to form a substantially integral, yet perforated and highly porous chemical filter element 16. Where the pellets 18 are joined together in this way, the frame member 17 is not needed, and may be omitted if desired.

During use, hot oil slowly flows past the basic conditioner in the chemically active filter  
20 element, and the basic salt thereof acts to counteract and neutralize acidic combustion products. This neutralization of acidic combustion products allows for a much longer useful life of additives such as, for example, dispersants and zinc dialkyldithiophosphate (ZDP), which are provided in

the oil by the manufacturer. This, in turn, allows for greater intervals between oil changes than is possible without the chemically active filter element.

Referring now to Figure 4, a cross-section of an oil filter 210 in connection with a second embodiment is shown. The oil filter 210 in this embodiment generally includes a cylindrical

5 housing 211 which defines a hollow space 214 therein, a porous mechanically active filter element 215 within that space, and a chemically active filter element 216, made up of a plurality of individual composite pellets 218, also retained within the hollow space inside the housing and disposed within the mechanically active filter element. As noted in connection with the first embodiment 10, the individual pellets 218 making up the chemically active filter element 216 may be bonded together or otherwise cohesively associated with one another to form a substantially integral, yet highly porous filter element 216 capable of independently supporting itself. With the exception of the configuration and placement of the respective mechanical and chemical filter elements 215, 216 as specified in this section, the oil filter 210 is substantially identical to the oil filter 10 of the first embodiment, as described hereinabove.

15 In the embodiment 210 of Figure 4, the mechanically active filter element 215 is a conventional cylindrical member made of accordion-pleated filter paper.

The chemically active filter element 216 is also provided in the shape of a cylinder in this embodiment, and is disposed radially and coaxially outside of the mechanically active filter element 215. A foraminous cylindrical screen or support frame 217 may, optionally, be provided within the housing 211 to supportively hold the filter elements 215, 216 therein. In this second embodiment 20 the chemically active filter element 216 is located outside of, and therefore upstream of the mechanical filter element 215, in order to allow chemical modification of acids or

other unwanted contaminants which may be present in the oil, with the basic conditioner of the chemical filter element 216, prior to mechanical filtration. In this second embodiment 210, the top and bottom horizontal segments 220, 222 of the frame member 217 have been extended outwardly towards the outer wall of the 219 of the housing 211, as compared to the frame

5 member 17 from the first embodiment, to contain the pellets 218 of the chemically active filter element therebetween. However, the portion of the frame member bottom horizontal segment 222 below the chemical filter element 216 is made foraminous, as shown, to allow oil to flow freely therethrough. The vertical inner wall 224 of the frame member 217 is also necessarily foraminous to allow oil flow therethrough.

10 Referring now to Figure 5, an oil filter 310 in accordance with a third embodiment of the present invention is shown. With the exception of the configuration and placement of the respective mechanical and chemical filter elements 315, 316 and related components, and unless otherwise specified in this section, the oil filter 310 is substantially identical to the oil filter 10 of the first embodiment, as described hereinabove.

15 The oil filter 310 in this embodiment generally includes a hollow cylindrical housing 311 which defines a chamber 314 therein, a porous mechanically active filter element 315 within that chamber, and a chemically active filter element 316, made up of a plurality of individual composite pellets 318, also retained within the chamber inside the housing and disposed below and before the mechanically active filter element. The pellets 318 are selected for size so as to make the best  
20 effect of the interstices therebetween. Once again, the flow path through the filter is shown by the arrows in the drawing.

As noted in connection with the first embodiment 10, the individual pellets 318 making up

the chemically active filter element 316 may be bonded together or otherwise cohesively associated with one another to form a substantially integral, yet highly porous filter element 316 capable of independently supporting itself.

In the embodiment 310 of Figure 5, the mechanically active filter element 315 is a

5 conventional cylindrical member made of accordion-pleated filter paper. A selectively foraminous cylindrical screen or support frame 317 may, optionally, be provided within the housing 311 to supportively hold the mechanically active filter element 315 therein. Also in this embodiment, porous annular upper and lower foraminous dividers 320, 322, respectively, may be placed above and/or below the chemically active filter element 316 to retain the pellets 318 of the chemically  
10 active filter element therebetween. The dividers 320 or 322 may be selectively foraminous solid plates or may be mesh screens. The upper divider 320 is constructed and arranged to pass oil only to the outside surface of the mechanically active filter element 315, so that the oil must be mechanically filtered before exiting the filter 310.

The chemically active filter element 316 is also provided in the shape of a cylinder in this  
15 embodiment, and is disposed below the mechanically active filter element 315. In this embodiment 310 the chemically active filter element 316 is located below the mechanical filter element 315, and therefore precedes the mechanical filter element in the flow path, in order to allow chemical modification of acids or other unwanted contaminants which may be present in the oil, with the basic conditioner of the chemically active filter element 316, prior to mechanical  
20 filtration. This design ensures that the oil will pass completely through the chemically active filter element before it reaches the mechanically active filter element, and provides more and longer-

lasting interaction between the oil and the chemically active filter element than the design of Figure 4.

Referring now to Figure 6, an oil filter assembly 410 in accordance with a fourth embodiment of the present invention is shown. The oil filter assembly 410 in this embodiment includes two primary parts, a conventional oil filter 402 shown on top in the drawing, and a supplemental cartridge 404, shown below the conventional filter.

The conventional oil filter 402 incorporates a mechanically active filter element 415 within a cylindrical housing 411. The conventional oil filter 402 further includes a base plate 420, which includes a plurality of inlet ports 422 arranged in a circular pattern as well as a central outlet port 424. The base plate 420 is provided as an integral part of the cylindrical housing 411, and an annular sealing member 425 fits engagingly into a groove 426 formed at the bottom surface of the base plate. The outlet port 424 has a plurality of female threads formed therein to allow rotatable mounting of the filter 402 on an externally threaded hollow tubular male connector fitting 409 of the supplemental cartridge 404.

The supplemental cartridge 404 is made to rotatably and threadably attach to an externally threaded hollow tubular fitting on an engine block (not shown), and to then have the conventional filter 402 rotatably and threadably fit thereon. The supplemental cartridge 404 includes a cylindrical housing 405 having a side wall 406, a base plate 407, sealably connected to the bottom edge of the side wall, and a cover plate 408 sealably connected to the top edge of the side wall.

The cover plate 408 has a plurality of outlet openings 412 formed therein above the chemically active filter member 416 to allow oil to flow outwardly from the supplemental cartridge 404 and then into the inlets 422 of the conventional oil filter 402.

The base plate 407 of the supplemental cartridge 404 includes a plurality of inlet ports 432, arranged in a circular pattern, as well as a central outlet port 434. The base plate 407 is provided as an integral part of the cylindrical housing 405, and an annular sealing member 435 fits engagingly into a groove 436 formed at the bottom surface of the base plate. The outlet port 434

5 has a plurality of female threads formed therein to allow rotatable mounting of the supplemental cartridge 404 to an externally threaded hollow tubular fitting on an engine block (not shown)

The hollow tubular male connector fitting 409, which is externally threaded, is provided at the center of the cover plate 408, and a cylindrical dividing wall member 403 is centrally disposed within the cartridge housing 405, and forms a fluid seal at the top and bottom surfaces thereof.

10 The cylindrical dividing wall member 403 is preferably made of an oil-tolerant elastomer.

The supplemental cartridge 404 contains a chemically active filter element 416 therein. The chemically active filter element 416 is made up of a plurality of individual composite pellets 418, retained within the hollow space inside the cartridge housing 405 and disposed radially outside of the cylindrical dividing wall member 403.

15 As noted in connection with the first embodiment 10, the individual pellets 418 making up the chemically active filter element 416 may be bonded together or otherwise cohesively associated with one another to form a substantially integral, yet highly porous filter element capable of independently supporting itself.

Also in this embodiment, a porous, annular lower mesh screen 419 may be placed below  
20 the chemically active filter element 416 to retain the pellets 418 of the chemically active filter element thereabove. Where used, the mesh screen 419 may rest on a transverse horizontal flange 429, which is an integral part of the cylindrical dividing wall member 403.

When the conventional oil filter 402 is attached to the supplemental cartridge 404, the total assembly 410 functions in a manner similar to the oil filter 310 of Figure 5.

The chemically active filter element 416 is also provided in the shape of a cylinder in this embodiment, and when the entire assembly 410 is considered as a whole, the chemically active  
5 filter element is disposed below the mechanically active filter element 415 of the conventional oil filter 402, and therefore precedes the mechanical filter element in the flow path, in order to allow chemical modification of acids or other unwanted contaminants which may be present in the oil, with the basic conditioner of the chemically active filter element 416, prior to mechanical  
10 filtration. This design ensures that the oil will pass completely through the chemically active filter element 416 before it reaches the mechanically active filter element 415, and provides more and longer-lasting interaction between the oil and the chemically active filter element than the design of Figure 4.

Optionally, as shown in Figure 7, the supplemental cartridge 404 may include a pair of hollow tubes 437, 438 attached to the side wall 406 thereof, which communicate with the interior  
15 of the cartridge housing 405. Where used, these tubes 427, 438 are provided to allow connection of the supplemental cartridge to a heat exchanger 440 to allow cooling of the oil which passes therethrough.

Although the present invention has been described herein with respect to a preferred embodiment thereof, the foregoing description is intended to be illustrative, and not restrictive.  
20 Those skilled in the art will realize that many modifications of the preferred embodiment could be made which would be operable. All such modifications, which are within the scope of the claims, are intended to be within the scope and spirit of the present invention.
